Significant increases in the etch rates of both GaAs and GaN have been observed with the addition of  $\text{SF}_6$  to  $\text{BCl}_3$  plasmas. Mass spectrometric characterization of neutrals in these gas mixtures shows that increasing the  $\text{SF}_6$  percentage in the flow enhances the dissociation of  $\text{BCl}_3$ , resulting in nearly 100% dissociation at 70%  $\text{SF}_6$ . This increased dissociation is believed to be due to electron attachment heating. Both Cl and  $\text{Cl}_2$  mass intensities also maximize at 70%  $\text{SF}_6$ . The detection of  $\text{BClF}$  and  $\text{BCl}_2\text{F}$  suggest the possibility of reactions occurring between  $\text{BCl}$  and  $\text{BCl}_2$  radicals and fluorine, which may inhibit the recombination of Cl. © 2000 American Institute of Physics. ## I. INTRODUCTION

Boron trichloride ( $\text{BCl}_3$ ) and sulfur hexafluoride ( $\text{SF}_6$ ) plasmas have been used to selectively etch GaAs over Al-GaAs for the fabrication of gallium arsenide based field effect transistors,<sup>1,2</sup> and to etch GaN.<sup>3,4</sup> For both applications, a significant increase in the etch rate has been observed with the addition of  $\text{SF}_6$  to the  $\text{BCl}_3$  plasmas. Previous microwave measurements on these gas mixtures showed that the electron density decreased with increasing  $\text{SF}_6$  percentage, and optical emission actinometry with argon indicated an increase in the electron temperature due to electron attachment heating.<sup>5</sup> Although the optical emission from molecular chlorine (normalized to the argon emission) showed an increase in the ground state concentration for low percentages of  $\text{SF}_6$ , there was some doubt as to the validity of actinometry because of the shift in the electron density distribution function.<sup>5</sup> Shul *et al.* observed an increase in the atomic chlorine mass signal with the addition of  $\text{SF}_6$  and assumed that the dissociation of  $\text{BCl}_3$  was increasing.<sup>3</sup> In this article, mass spectrometric characterization of  $\text{BCl}_3/\text{SF}_6$  plasmas is presented. The relative concentrations of  $\text{BCl}_3$  and neutral radical species within the plasma are examined as functions of  $\text{SF}_6$  percentage in the flow and dc bias (rf power).

## II. EXPERIMENTAL PROCEDURE

The characterization of the  $\text{BCl}_3/\text{SF}_6$  plasmas was performed in a 600 amu VG Quadrupoles SXP Elite mass spectrometry system which was connected to the Plasma Therm 790 reactive ion etching plasma chamber via one of the viewports. Discharge species were sampled through a 100  $\mu\text{m}$  diameter orifice, and sampling pressures within the mass spectrometer chamber were on the order of  $10^{-7}$  torr to reduce recombination reactions within the analyzer. The emission current of the spectrometer was kept below 0.3 mA to minimize the effect of the thermal dissociation of neutral species caused by hot electron emission from the filament.

To be sure that the mass signals were originating only from neutrals in the plasma, and not from dissociative ionization within the mass spectrometer itself, the method of appearance mass spectrometry was employed.<sup>6</sup> This technique is based on the several electron volt energy difference between the appearance potentials for electron-impact ionization and the energy for dissociative ionization of parent molecules. For radicals such as  $\text{BCl}_2$ ,  $\text{Cl}_2$ , and Cl, the electron energy was set below the threshold appearance energy needed to observe the mass signal with the plasma off. An electron energy of 35 eV was used to monitor  $\text{BCl}_3$  for the dissociation measurements.

## III. RESULTS AND DISCUSSION

The GaAs etch rate at 50 mTorr as a function of  $\text{SF}_6$  percentage in the flow is shown in Fig. 1. The rf power and total flow were held constant at 150 W and 20 sccm, respectively. The decrease in the bias voltage with increasing  $\text{SF}_6$  addition is also shown (and is consistent with the fact that the electron density decreases due to attachment with an increasing  $\text{SF}_6$  percentage in the flow<sup>5</sup>). The etch rate increases from 90 Å/min in pure  $\text{BCl}_3$  to 5500 Å/min at 55%  $\text{SF}_6$ . Shul *et al.* have also observed an increase in the etch rate of GaN as a function of  $\text{SF}_6$  percentage in an inductively coupled plasma system.<sup>3,4</sup>

The quadrupole mass spectrometer (QMS) intensities of  $\text{BCl}_3$ ,  $\text{BCl}_2$ ,  $\text{Cl}_2$ , and Cl as a function of  $\text{SF}_6$  percentage in the flow are shown in Fig. 2. No mass signal corresponding to  $\text{BCl}$  was apparent. The rf power, pressure, and total flow were held constant at 200 W, 50 mTorr, and 20 sccm, respectively. The curves for both  $\text{Cl}_2$  and Cl exhibit maxima at approximately 70%  $\text{SF}_6$ . The  $\text{Cl}_2$  intensity increased by a factor of 38 and the Cl intensity increased by about 5 times. The increase in etch rate observed in Fig. 1 is no doubt due to the increased chlorine production. As expected, both  $\text{Cl}_2$  and Cl intensities decrease to zero for 100%  $\text{SF}_6$  (0%  $\text{BCl}_3$ ). Overall, the  $\text{Cl}_2$  intensity is significantly higher than the Cl intensity. Recombination of Cl to form  $\text{Cl}_2$  during transport to the mass spectrometer could account for the low Cl inten-

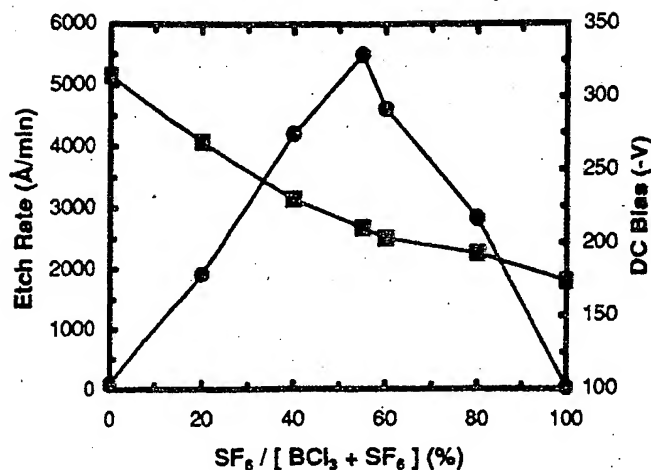

FIG. 1. Etch rate of GaAs (●) as a function of percent SF<sub>6</sub> in the flow for constant power (150 W, 50 mTorr, and 20 sccm). dc bias (■) is also shown.

sity. Figure 2 also shows that the BCl<sub>2</sub> intensity is very small for low SF<sub>6</sub> percentages, and essentially nonexistent for SF<sub>6</sub> percentages above 30%.

The dependence of the mass intensities of neutral species as a function of dc bias was also investigated and is shown in Fig. 3. The SF<sub>6</sub> percentage in flow was 70%, the total flow was 20 sccm, and the pressure was maintained at 50 mTorr. The intensity of BCl<sub>3</sub> decreases sharply with increasing dc bias and drops to almost zero at -50 V, indicating significant dissociation of BCl<sub>3</sub>. The Cl<sub>2</sub> mass signal increases rapidly for this same range and then increases at a much slower rate for higher biases. The Cl intensity also increases initially and then saturates. The initial increases in both the Cl and Cl<sub>2</sub> mass intensities can be attributed to increased dissociation of BCl<sub>3</sub>. The slower increase in the Cl<sub>2</sub> intensity at biases above -50 V may be due to dissociation of radicals such as BCl<sub>2</sub>. The observed saturation region for Cl may be due to the recombination of Cl radicals to form Cl<sub>2</sub>.

The dissociation of BCl<sub>3</sub> was measured as a function of rf power with SF<sub>6</sub> percentage as a parameter and the results are shown in Fig. 4. The pressure in the system was 50 mTorr. The dissociation of BCl<sub>3</sub> was defined as the QMS

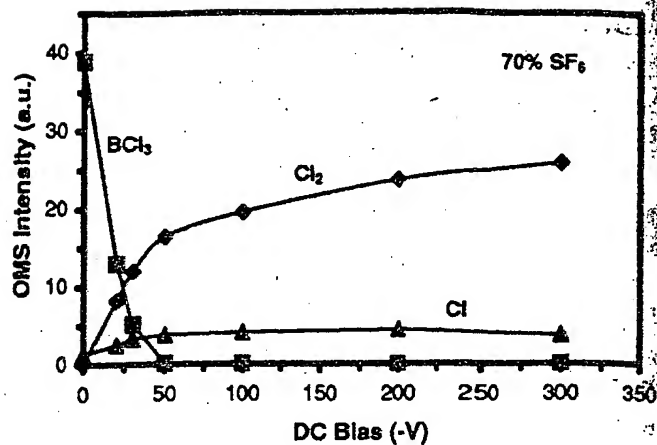

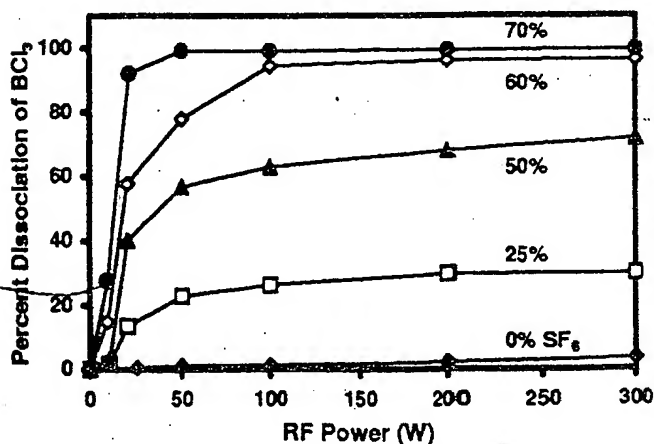

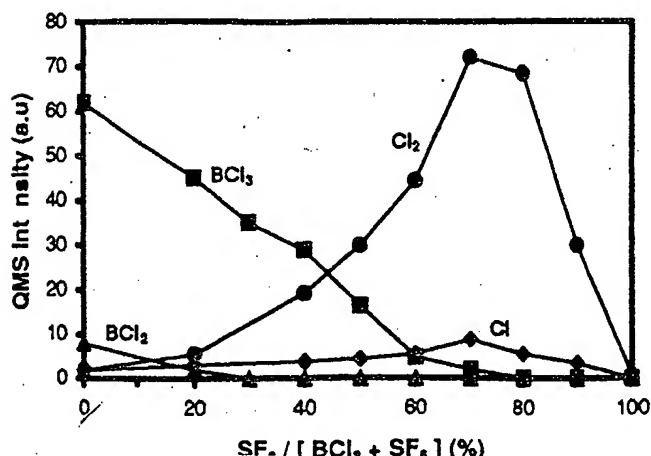

FIG. 3. QMS intensities of BCl<sub>3</sub>, Cl<sub>2</sub>, and Cl as functions of dc bias (20 sccm and 50 mTorr).

intensity difference of the BCl<sub>3</sub> peak with plasma on and off divided by the intensity while off. The dissociation of BCl<sub>3</sub> increased with increasing rf power regardless of the percentage of SF<sub>6</sub> in the flow. This is consistent with the fact that higher rf power results in higher electron densities, which should enhance the BCl<sub>3</sub> dissociation. For the 0% SF<sub>6</sub> curve, the dissociation of BCl<sub>3</sub> is very low and shows only a slight increase with increasing rf power. This explains the very low etch rate of GaAs in pure BCl<sub>3</sub> plasmas observed in Fig. 1. For constant rf power, the dissociation of BCl<sub>3</sub> increases with increasing SF<sub>6</sub> percentage. At 70% SF<sub>6</sub> and an rf power of 200 W, there is nearly 100% dissociation of the BCl<sub>3</sub>. For constant power, the electron density decreases with increasing SF<sub>6</sub> percentage as a result of electron attachment.<sup>5</sup> In order to dissipate the same amount of power the average energy of the remaining electrons must increase (a phenomenon known as electron attachment heating). The enhanced dissociation of BCl<sub>3</sub> is most likely due to this increase in average electron energy.

The appearance of mass signals for BCIF and BCl<sub>2</sub>F for different chlorine and boron isotopes were observed with the addition of SF<sub>6</sub>. The mass intensities of BCIF (<sup>10</sup>B<sup>35</sup>ClF at *m/e* = 63.98, <sup>11</sup>B<sup>35</sup>ClF at *m/e* = 64.98, and <sup>11</sup>B<sup>37</sup>ClF at *m/e*

=66.97) as a function of SF<sub>6</sub> percentage in the flow are shown in Fig. 5. The BCl<sub>2</sub>F mass signals (<sup>10</sup>B<sup>35</sup>Cl<sub>2</sub>F at *m/e* = 98.94, <sup>11</sup>B<sup>35</sup>Cl<sub>2</sub>F at *m/e* = 99.95, and <sup>10</sup>B<sup>35</sup>Cl<sup>37</sup>ClF at *m/e* = 100.94) were also monitored as a function of SF<sub>6</sub> percentage in the total flow and are shown in Fig. 6. The rf power, pressure, and total flow were held constant at 200 W, 50 mTorr, and 20 sccm, respectively. The occurrence of any BCIF or BCl<sub>2</sub>F signals at 0% SF<sub>6</sub> is believed to be due to residual fluorine in the chamber. A significant increase in the mass peak intensities of BCIF and BCl<sub>2</sub>F were observed as the SF<sub>6</sub> percentage increased and both exhibited maxima at 30% SF<sub>6</sub>. It is possible that fluorine from SF<sub>6</sub> reacts with the BCl and BCl<sub>2</sub> radicals to form BCIF and BCl<sub>2</sub>F. This could explain why the BCl<sub>2</sub> mass peak intensity in Fig. 2 is almost zero at 30% SF<sub>6</sub>, and why no BCl mass signal was observed.

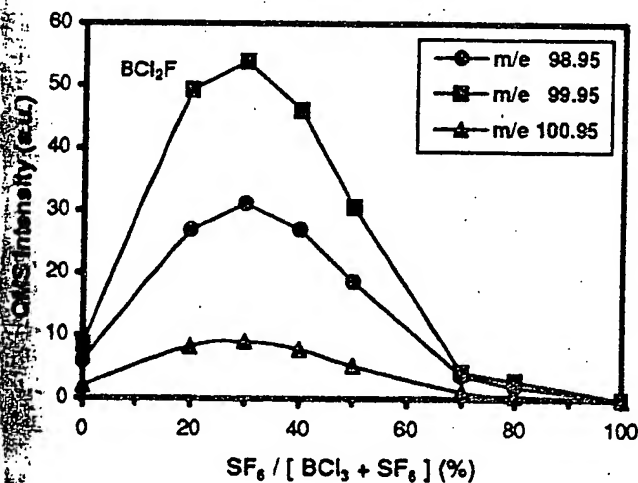

FIG. 6. QMS intensities of BCl<sub>2</sub>F for different isotopes of chlorine and boron as functions of SF<sub>6</sub> percentage in the flow (200 W, 50 mTorr, and 20 sccm).

There is some uncertainty as to whether these reactions occur in the plasma chamber or between the chamber and the mass spectrometer. However, previous experimental results have indicated that the F\* optical emission intensity is essentially zero until the SF<sub>6</sub> percentage is increased to 70%.<sup>5</sup> At 70% SF<sub>6</sub>, the mass peak intensities of both BCIF and BCl<sub>2</sub>F approach zero (see Figs. 5 and 6). Since these trends are consistent with one another, it would appear that the formation of BCIF and BCl<sub>2</sub>F occurs in the plasma chamber. The formation of BCIF and BCl<sub>2</sub>F would help to prevent BCl and BCl<sub>2</sub> radicals from recombining with chlorine, thus reducing two possible loss mechanisms for chlorine radicals.

The addition of SF<sub>6</sub> results in an increase in the dissociation of BCl<sub>3</sub> and a subsequent increase in chlorine radical concentrations, hence accounting for the increase in the GaAs etch rate observed in Fig. 1. The dissociation of BCl<sub>3</sub> and the chlorine radical densities exhibit maxima at 70% SF<sub>6</sub> but the GaAs etch rate peaks near 55% SF<sub>6</sub>. The shift between the maxima in etch rate and the peaks in the chlorine radical densities could be attributed to the formation of non-volatile GaF<sub>3</sub> which would compete with the etch process.

#### IV. SUMMARY

Mass spectrometric analysis of BCl<sub>3</sub>/SF<sub>6</sub> plasmas has shown that the dissociation of BCl<sub>3</sub> increases with the addition of SF<sub>6</sub>, and results in nearly 100% dissociation of BCl<sub>3</sub> for 70% SF<sub>6</sub> in the flow. The enhanced dissociation is believed to be due to an increase in the average electron temperature as a result of electron attachment heating. Both the Cl<sub>2</sub> and Cl concentrations also exhibited maxima for 70% SF<sub>6</sub> in BCl<sub>3</sub>. The increase in the dissociation of BCl<sub>3</sub> and subsequent increase in chlorine radical concentrations accounts for the observed increase in etch rate. In addition, two new species, BCl and BCl<sub>2</sub>F, were detected in these gas mixtures. Their formation might help to prevent BCl and BCl<sub>2</sub> radicals from recombining with chlorine, thus reducing two possible loss mechanisms for chlorine radicals.
